

# Lecture 14:

# Reinforcement Learning

# Administrative

**A3 due Wed 5/22**

**Milestone feedback will be released soon.**

**Some students haven't filled out project registration form yet. If you didn't, your milestone has \*NOT\* been graded. If you are in this case, you need to fill out project registration form ASAP and make a private piazza post to get your milestone graded.**

# So far... Supervised Learning

**Data:**  $(x, y)$

$x$  is data,  $y$  is label

**Goal:** Learn a *function* to map  $x \rightarrow y$

**Examples:** Classification,  
regression, object detection,  
semantic segmentation, image  
captioning, etc.

→ Cat

Classification

[This image is CC0 public domain](#)

# So far... Unsupervised Learning

**Data:**  $x$

Just data, no labels!

**Goal:** Learn some underlying hidden *structure* of the data

**Examples:** Clustering, dimensionality reduction, feature learning, density estimation, etc.

# Today: Reinforcement Learning

Problems involving an **agent** interacting with an **environment**, which provides numeric **reward** signals

**Goal:** Learn how to take actions in order to maximize reward

Atari games figure copyright Volodymyr Mnih et al., 2013. Reproduced with permission.

# Overview

- What is Reinforcement Learning?
- Markov Decision Processes
- Q-Learning
- Policy Gradients

# Reinforcement Learning

Agent

The diagram illustrates the basic components of Reinforcement Learning. It consists of two rectangular boxes arranged vertically. The top box is light orange with an orange border and contains the word 'Agent' in orange text. The bottom box is light blue with a blue border and contains the word 'Environment' in blue text. There are no arrows or other graphical elements connecting the two boxes.

Environment

# Reinforcement Learning

# Reinforcement Learning

# Reinforcement Learning

# Reinforcement Learning

# Cart-Pole Problem

**Objective:** Balance a pole on top of a movable cart

**State:** angle, angular speed, position, horizontal velocity

**Action:** horizontal force applied on the cart

**Reward:** 1 at each time step if the pole is upright

[This image is CC0 public domain](#)

# Robot Locomotion

**Objective:** Make the robot move forward

**State:** Angle and position of the joints

**Action:** Torques applied on joints

**Reward:** 1 at each time step upright + forward movement

Figures copyright John Schulman et al., 2016. Reproduced with permission.

# Atari Games

**Objective:** Complete the game with the highest score

**State:** Raw pixel inputs of the game state

**Action:** Game controls e.g. Left, Right, Up, Down

**Reward:** Score increase/decrease at each time step

Figures copyright Volodymyr Mnih et al., 2013. Reproduced with permission.

# Go

**Objective:** Win the game!

**State:** Position of all pieces

**Action:** Where to put the next piece down

**Reward:** 1 if win at the end of the game, 0 otherwise

[This image is CC0 public domain](#)

# How can we mathematically formalize the RL problem?

# Markov Decision Process

- Mathematical formulation of the RL problem
- **Markov property**: Current state completely characterises the state of the world

Defined by:  $(\mathcal{S}, \mathcal{A}, \mathcal{R}, \mathbb{P}, \gamma)$

$\mathcal{S}$  : set of possible states

$\mathcal{A}$  : set of possible actions

$\mathcal{R}$  : distribution of reward given (state, action) pair

$\mathbb{P}$  : transition probability i.e. distribution over next state given (state, action) pair

$\gamma$  : discount factor

# Markov Decision Process

- At time step  $t=0$ , environment samples initial state  $s_0 \sim p(s_0)$
- Then, for  $t=0$  until done:
  - Agent selects action  $a_t$
  - Environment samples reward  $r_t \sim R(\cdot | s_t, a_t)$
  - Environment samples next state  $s_{t+1} \sim P(\cdot | s_t, a_t)$
  - Agent receives reward  $r_t$  and next state  $s_{t+1}$
- A policy  $\pi$  is a function from  $S$  to  $A$  that specifies what action to take in each state
- **Objective:** find policy  $\pi^*$  that maximizes cumulative discounted reward:  $\sum_{t \geq 0} \gamma^t r_t$

# A simple MDP: Grid World

actions = {

1. right 

2. left 

3. up 

4. down 

}

states

Set a negative “reward”  
for each transition  
(e.g.  $r = -1$ )

**Objective:** reach one of terminal states (greyed out) in  
least number of actions

# A simple MDP: Grid World

Random Policy

Optimal Policy

# The optimal policy $\pi^*$

We want to find optimal policy  $\pi^*$  that maximizes the sum of rewards.

# The optimal policy $\pi^*$

We want to find optimal policy  $\pi^*$  that maximizes the sum of rewards.

How do we handle the randomness (initial state, transition probability...)?

Maximize the **expected sum of rewards!**

# The optimal policy $\pi^*$

We want to find optimal policy  $\pi^*$  that maximizes the sum of rewards.

How do we handle the randomness (initial state, transition probability...)?

Maximize the **expected sum of rewards!**

$$\text{Formally: } \pi^* = \arg \max_{\pi} \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t | \pi \right] \quad \text{with } s_0 \sim p(s_0), a_t \sim \pi(\cdot | s_t), s_{t+1} \sim p(\cdot | s_t, a_t)$$

# Definitions: Value function and Q-value function

Following a policy produces sample trajectories (or paths)  $s_0, a_0, r_0, s_1, a_1, r_1, \dots$

# Definitions: Value function and Q-value function

Following a policy produces sample trajectories (or paths)  $s_0, a_0, r_0, s_1, a_1, r_1, \dots$

How good is a state?

The **value function** at state  $s$ , is the expected cumulative reward from following the policy from state  $s$ :

$$V^\pi(s) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, \pi \right]$$

# Definitions: Value function and Q-value function

Following a policy produces sample trajectories (or paths)  $s_0, a_0, r_0, s_1, a_1, r_1, \dots$

## How good is a state?

The **value function** at state  $s$ , is the expected cumulative reward from following the policy from state  $s$ :

$$V^\pi(s) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, \pi \right]$$

## How good is a state-action pair?

The **Q-value function** at state  $s$  and action  $a$ , is the expected cumulative reward from taking action  $a$  in state  $s$  and then following the policy:

$$Q^\pi(s, a) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, a_0 = a, \pi \right]$$

# Bellman equation

The optimal Q-value function  $Q^*$  is the maximum expected cumulative reward achievable from a given (state, action) pair:

$$Q^*(s, a) = \max_{\pi} \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, a_0 = a, \pi \right]$$

# Bellman equation

The optimal Q-value function  $Q^*$  is the maximum expected cumulative reward achievable from a given (state, action) pair:

$$Q^*(s, a) = \max_{\pi} \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, a_0 = a, \pi \right]$$

$Q^*$  satisfies the following **Bellman equation**:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') \mid s, a \right]$$

**Intuition:** if the optimal state-action values for the next time-step  $Q^*(s', a')$  are known, then the optimal strategy is to take the action that maximizes the expected value of  $r + \gamma Q^*(s', a')$

# Bellman equation

The optimal Q-value function  $Q^*$  is the maximum expected cumulative reward achievable from a given (state, action) pair:

$$Q^*(s, a) = \max_{\pi} \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid s_0 = s, a_0 = a, \pi \right]$$

$Q^*$  satisfies the following **Bellman equation**:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') \mid s, a \right]$$

**Intuition:** if the optimal state-action values for the next time-step  $Q^*(s', a')$  are known, then the optimal strategy is to take the action that maximizes the expected value of  $r + \gamma Q^*(s', a')$

The optimal policy  $\pi^*$  corresponds to taking the best action in any state as specified by  $Q^*$

# Solving for the optimal policy

**Value iteration** algorithm: Use Bellman equation as an iterative update

$$Q_{i+1}(s, a) = \mathbb{E} \left[ r + \gamma \max_{a'} Q_i(s', a') | s, a \right]$$

$Q_i$  will converge to  $Q^*$  as  $i \rightarrow \text{infinity}$

# Solving for the optimal policy

**Value iteration** algorithm: Use Bellman equation as an iterative update

$$Q_{i+1}(s, a) = \mathbb{E} \left[ r + \gamma \max_{a'} Q_i(s', a') | s, a \right]$$

$Q_i$  will converge to  $Q^*$  as  $i \rightarrow \text{infinity}$

What's the problem with this?

# Solving for the optimal policy

**Value iteration** algorithm: Use Bellman equation as an iterative update

$$Q_{i+1}(s, a) = \mathbb{E} \left[ r + \gamma \max_{a'} Q_i(s', a') | s, a \right]$$

$Q_i$  will converge to  $Q^*$  as  $i \rightarrow \infty$

What's the problem with this?

Not scalable. Must compute  $Q(s, a)$  for every state-action pair. If state is e.g. current game state pixels, computationally infeasible to compute for entire state space!

# Solving for the optimal policy

**Value iteration** algorithm: Use Bellman equation as an iterative update

$$Q_{i+1}(s, a) = \mathbb{E} \left[ r + \gamma \max_{a'} Q_i(s', a') | s, a \right]$$

$Q_i$  will converge to  $Q^*$  as  $i \rightarrow \text{infinity}$

What's the problem with this?

Not scalable. Must compute  $Q(s, a)$  for every state-action pair. If state is e.g. current game state pixels, computationally infeasible to compute for entire state space!

**Solution:** use a function approximator to estimate  $Q(s, a)$ . E.g. a neural network!

# Solving for the optimal policy: Q-learning

Q-learning: Use a function approximator to estimate the action-value function

$$Q(s, a; \theta) \approx Q^*(s, a)$$

# Solving for the optimal policy: Q-learning

Q-learning: Use a function approximator to estimate the action-value function

$$Q(s, a; \theta) \approx Q^*(s, a)$$

If the function approximator is a deep neural network => **deep q-learning!**

# Solving for the optimal policy: Q-learning

Q-learning: Use a function approximator to estimate the action-value function

$$Q(s, a; \theta) \approx Q^*(s, a)$$

 function parameters (weights)

If the function approximator is a deep neural network => **deep q-learning!**

# Solving for the optimal policy: Q-learning

Remember: want to find a Q-function that satisfies the Bellman Equation:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') | s, a \right]$$

# Solving for the optimal policy: Q-learning

Remember: want to find a Q-function that satisfies the Bellman Equation:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') | s, a \right]$$

## Forward Pass

Loss function:  $L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot)} [(y_i - Q(s, a; \theta_i))^2]$

where  $y_i = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) | s, a \right]$

# Solving for the optimal policy: Q-learning

Remember: want to find a Q-function that satisfies the Bellman Equation:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') | s, a \right]$$

## Forward Pass

Loss function:  $L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot)} [(y_i - Q(s, a; \theta_i))^2]$

where  $y_i = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) | s, a \right]$

## Backward Pass

Gradient update (with respect to Q-function parameters  $\theta$ ):

$$\nabla_{\theta_i} L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot); s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) - Q(s, a; \theta_i) \right] \nabla_{\theta_i} Q(s, a; \theta_i)$$

# Solving for the optimal policy: Q-learning

Remember: want to find a Q-function that satisfies the Bellman Equation:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') | s, a \right]$$

## Forward Pass

Loss function:  $L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot)} [(y_i - Q(s, a; \theta_i))^2]$

where  $y_i = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) | s, a \right]$

Iteratively try to make the Q-value close to the target value ( $y_i$ ) it should have, if Q-function corresponds to optimal  $Q^*$  (and optimal policy  $\pi^*$ )

## Backward Pass

Gradient update (with respect to Q-function parameters  $\theta$ ):

$$\nabla_{\theta_i} L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot); s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) - Q(s, a; \theta_i) \right] \nabla_{\theta_i} Q(s, a; \theta_i)$$

# Case Study: Playing Atari Games

**Objective:** Complete the game with the highest score

**State:** Raw pixel inputs of the game state

**Action:** Game controls e.g. Left, Right, Up, Down

**Reward:** Score increase/decrease at each time step

Figures copyright Volodymyr Mnih et al., 2013. Reproduced with permission.

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

← Input: state  $s_t$

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

← Familiar conv layers,  
FC layer

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

← Last FC layer has 4-d output (if 4 actions), corresponding to  $Q(s_t, a_1)$ ,  $Q(s_t, a_2)$ ,  $Q(s_t, a_3)$ ,  $Q(s_t, a_4)$

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

← Last FC layer has 4-d output (if 4 actions), corresponding to  $Q(s_t, a_1)$ ,  $Q(s_t, a_2)$ ,  $Q(s_t, a_3)$ ,  $Q(s_t, a_4)$

Number of actions between 4-18 depending on Atari game

# Q-network Architecture

$Q(s, a; \theta)$  :  
neural network  
with weights  $\theta$

A single feedforward pass  
to compute Q-values for all  
actions from the current  
state => efficient!

← Last FC layer has 4-d  
output (if 4 actions),  
corresponding to  $Q(s_t, a_1)$ ,  $Q(s_t, a_2)$ ,  $Q(s_t, a_3)$ ,  
 $Q(s_t, a_4)$

depending on Atari game

**Current state  $s_t$ : 84x84x4 stack of last 4 frames**  
(after RGB->grayscale conversion, downsampling, and cropping)

# Training the Q-network: Loss function (from before)

Remember: want to find a Q-function that satisfies the Bellman Equation:

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') | s, a \right]$$

## Forward Pass

Loss function:  $L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot)} [(y_i - Q(s, a; \theta_i))^2]$

where  $y_i = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) | s, a \right]$

Iteratively try to make the Q-value close to the target value ( $y_i$ ) it should have, if Q-function corresponds to optimal  $Q^*$  (and optimal policy  $\pi^*$ )

## Backward Pass

Gradient update (with respect to Q-function parameters  $\theta$ ):

$$\nabla_{\theta_i} L_i(\theta_i) = \mathbb{E}_{s, a \sim \rho(\cdot); s' \sim \mathcal{E}} \left[ (r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) - Q(s, a; \theta_i)) \nabla_{\theta_i} Q(s, a; \theta_i) \right]$$

# Training the Q-network: Experience Replay

Learning from batches of consecutive samples is problematic:

- Samples are correlated => inefficient learning
- Current Q-network parameters determines next training samples (e.g. if maximizing action is to move left, training samples will be dominated by samples from left-hand size) => can lead to bad feedback loops

# Training the Q-network: Experience Replay

Learning from batches of consecutive samples is problematic:

- Samples are correlated => inefficient learning
- Current Q-network parameters determines next training samples (e.g. if maximizing action is to move left, training samples will be dominated by samples from left-hand size) => can lead to bad feedback loops

Address these problems using **experience replay**

- Continually update a **replay memory** table of transitions ( $s_t, a_t, r_t, s_{t+1}$ ) as game (experience) episodes are played
- Train Q-network on random minibatches of transitions from the replay memory, instead of consecutive samples

# Training the Q-network: Experience Replay

Learning from batches of consecutive samples is problematic:

- Samples are correlated => inefficient learning
- Current Q-network parameters determines next training samples (e.g. if maximizing action is to move left, training samples will be dominated by samples from left-hand size) => can lead to bad feedback loops

Address these problems using **experience replay**

- Continually update a **replay memory** table of transitions ( $s_t, a_t, r_t, s_{t+1}$ ) as game (experience) episodes are played
- Train Q-network on random minibatches of transitions from the replay memory, instead of consecutive samples

Each transition can also contribute  
to multiple weight updates  
=> greater data efficiency

# Putting it together: Deep Q-Learning with Experience Replay

# Policy Gradients

What is a problem with Q-learning?

The Q-function can be very complicated!

Example: a robot grasping an object has a very high-dimensional state => hard to learn exact value of every (state, action) pair

# Policy Gradients

What is a problem with Q-learning?

The Q-function can be very complicated!

Example: a robot grasping an object has a very high-dimensional state => hard to learn exact value of every (state, action) pair

But the policy can be much simpler: just close your hand

Can we learn a policy directly, e.g. finding the best policy from a collection of policies?

# Policy Gradients

Formally, let's define a class of parameterized policies:  $\Pi = \{\pi_\theta, \theta \in \mathbb{R}^m\}$

For each policy, define its value:

$$J(\theta) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t | \pi_\theta \right]$$

# Policy Gradients

Formally, let's define a class of parameterized policies:  $\Pi = \{\pi_\theta, \theta \in \mathbb{R}^m\}$

For each policy, define its value:

$$J(\theta) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid \pi_\theta \right]$$

We want to find the optimal policy  $\theta^* = \arg \max_{\theta} J(\theta)$

How can we do this?

# Policy Gradients

Formally, let's define a class of parameterized policies:  $\Pi = \{\pi_\theta, \theta \in \mathbb{R}^m\}$

For each policy, define its value:

$$J(\theta) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t \mid \pi_\theta \right]$$

We want to find the optimal policy  $\theta^* = \arg \max_{\theta} J(\theta)$

How can we do this?

Gradient ascent on policy parameters!

# REINFORCE algorithm

Mathematically, we can write:

$$\begin{aligned} J(\theta) &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)] \\ &= \int_{\tau} r(\tau) p(\tau; \theta) d\tau \end{aligned}$$

Where  $r(\tau)$  is the reward of a trajectory  $\tau = (s_0, a_0, r_0, s_1, \dots)$

# REINFORCE algorithm

Expected reward:

$$\begin{aligned} J(\theta) &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)] \\ &= \int_{\tau} r(\tau) p(\tau; \theta) d\tau \end{aligned}$$

# REINFORCE algorithm

Expected reward:  $J(\theta) = \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)]$

$$= \int_{\tau} r(\tau) p(\tau; \theta) d\tau$$

Now let's differentiate this:  $\nabla_{\theta} J(\theta) = \int_{\tau} r(\tau) \nabla_{\theta} p(\tau; \theta) d\tau$

# REINFORCE algorithm

Expected reward:  $J(\theta) = \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)]$

$$= \int_{\tau} r(\tau) p(\tau; \theta) d\tau$$

Now let's differentiate this:  $\nabla_{\theta} J(\theta) = \int_{\tau} r(\tau) \nabla_{\theta} p(\tau; \theta) d\tau$

Intractable! Gradient of an expectation is problematic when  $p$  depends on  $\theta$

# REINFORCE algorithm

Expected reward:  $J(\theta) = \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)]$

$$= \int_{\tau} r(\tau) p(\tau; \theta) d\tau$$

Now let's differentiate this:  $\nabla_{\theta} J(\theta) = \int_{\tau} r(\tau) \nabla_{\theta} p(\tau; \theta) d\tau$

Intractable! Gradient of an expectation is problematic when  $p$  depends on  $\theta$

However, we can use a nice trick:  $\nabla_{\theta} p(\tau; \theta) = p(\tau; \theta) \frac{\nabla_{\theta} p(\tau; \theta)}{p(\tau; \theta)} = p(\tau; \theta) \nabla_{\theta} \log p(\tau; \theta)$

# REINFORCE algorithm

Expected reward:  $J(\theta) = \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)]$

$$= \int_{\tau} r(\tau) p(\tau; \theta) d\tau$$

Now let's differentiate this:  $\nabla_{\theta} J(\theta) = \int_{\tau} r(\tau) \nabla_{\theta} p(\tau; \theta) d\tau$

Intractable! Gradient of an expectation is problematic when  $p$  depends on  $\theta$

However, we can use a nice trick:  $\nabla_{\theta} p(\tau; \theta) = p(\tau; \theta) \frac{\nabla_{\theta} p(\tau; \theta)}{p(\tau; \theta)} = p(\tau; \theta) \nabla_{\theta} \log p(\tau; \theta)$

If we inject this back:

$$\begin{aligned} \nabla_{\theta} J(\theta) &= \int_{\tau} (r(\tau) \nabla_{\theta} \log p(\tau; \theta)) p(\tau; \theta) d\tau \\ &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau) \nabla_{\theta} \log p(\tau; \theta)] \end{aligned}$$

Can estimate with  
Monte Carlo sampling

# REINFORCE algorithm

Can we compute those quantities without knowing the transition probabilities?

We have:  $p(\tau; \theta) = \prod_{t \geq 0} p(s_{t+1} | s_t, a_t) \pi_{\theta}(a_t | s_t)$

# REINFORCE algorithm

Can we compute those quantities without knowing the transition probabilities?

We have:  $p(\tau; \theta) = \prod_{t \geq 0} p(s_{t+1} | s_t, a_t) \pi_{\theta}(a_t | s_t)$

Thus:  $\log p(\tau; \theta) = \sum_{t \geq 0} \log p(s_{t+1} | s_t, a_t) + \log \pi_{\theta}(a_t | s_t)$

# REINFORCE algorithm

Can we compute those quantities without knowing the transition probabilities?

We have:  $p(\tau; \theta) = \prod_{t \geq 0} p(s_{t+1} | s_t, a_t) \pi_{\theta}(a_t | s_t)$

Thus:  $\log p(\tau; \theta) = \sum_{t \geq 0} \log p(s_{t+1} | s_t, a_t) + \log \pi_{\theta}(a_t | s_t)$

And when differentiating:  $\nabla_{\theta} \log p(\tau; \theta) = \sum_{t \geq 0} \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

Doesn't depend on  
transition probabilities!

# REINFORCE algorithm

$$\begin{aligned}\nabla_{\theta} J(\theta) &= \int_{\tau} (r(\tau) \nabla_{\theta} \log p(\tau; \theta)) p(\tau; \theta) d\tau \\ &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau) \nabla_{\theta} \log p(\tau; \theta)]\end{aligned}$$

Can we compute those quantities without knowing the transition probabilities?

We have:  $p(\tau; \theta) = \prod_{t \geq 0} p(s_{t+1} | s_t, a_t) \pi_{\theta}(a_t | s_t)$

Thus:  $\log p(\tau; \theta) = \sum_{t \geq 0} \log p(s_{t+1} | s_t, a_t) + \log \pi_{\theta}(a_t | s_t)$

And when differentiating:  $\nabla_{\theta} \log p(\tau; \theta) = \sum_{t \geq 0} \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$  Doesn't depend on transition probabilities!

Therefore when sampling a trajectory  $\tau$ , we can estimate  $J(\theta)$  with

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# Intuition

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

**Interpretation:**

- If  $r(\tau)$  is high, push up the probabilities of the actions seen
- If  $r(\tau)$  is low, push down the probabilities of the actions seen

# Intuition

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

## Interpretation:

- If  $r(\tau)$  is high, push up the probabilities of the actions seen
- If  $r(\tau)$  is low, push down the probabilities of the actions seen

Might seem simplistic to say that if a trajectory is good then all its actions were good. **But in expectation, it averages out!**

# Intuition

Gradient estimator: 
$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

## Interpretation:

- If  $r(\tau)$  is high, push up the probabilities of the actions seen
- If  $r(\tau)$  is low, push down the probabilities of the actions seen

Might seem simplistic to say that if a trajectory is good then all its actions were good. **But in expectation, it averages out!**

However, this also suffers from high variance because credit assignment is really hard. Can we help the estimator?

# Variance reduction

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

# Variance reduction

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

**First idea:** Push up probabilities of an action seen, only by the cumulative future reward from that state

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} r_{t'} \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# Variance reduction

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

**First idea:** Push up probabilities of an action seen, only by the cumulative future reward from that state

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} r_{t'} \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

**Second idea:** Use discount factor  $\gamma$  to ignore delayed effects

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t'-t} r_{t'} \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# Variance reduction: Baseline

**Problem:** The raw value of a trajectory isn't necessarily meaningful. For example, if rewards are all positive, you keep pushing up probabilities of actions.

**What is important then?** Whether a reward is better or worse than what you expect to get

**Idea:** Introduce a baseline function dependent on the state.  
Concretely, estimator is now:

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t'-t} r_{t'} - b(s_t) \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# How to choose the baseline?

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t'-t} r_{t'} - b(s_t) \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

A simple baseline: constant moving average of rewards experienced so far from all trajectories

# How to choose the baseline?

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t'-t} r_{t'} - b(s_t) \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

A simple baseline: constant moving average of rewards experienced so far from all trajectories

Variance reduction techniques seen so far are typically used in “Vanilla REINFORCE”

# How to choose the baseline?

A better baseline: Want to push up the probability of an action from a state, if this action was better than the **expected value of what we should get from that state**.

Q: What does this remind you of?

# How to choose the baseline?

A better baseline: Want to push up the probability of an action from a state, if this action was better than the **expected value of what we should get from that state**.

Q: What does this remind you of?

A: Q-function and value function!

# How to choose the baseline?

A better baseline: Want to push up the probability of an action from a state, if this action was better than the **expected value of what we should get from that state**.

Q: What does this remind you of?

A: Q-function and value function!

Intuitively, we are happy with an action  $a_t$  in a state  $s_t$  if  $Q^\pi(s_t, a_t) - V^\pi(s_t)$  is large. On the contrary, we are unhappy with an action if it's small.

# How to choose the baseline?

A better baseline: Want to push up the probability of an action from a state, if this action was better than the **expected value of what we should get from that state**.

Q: What does this remind you of?

A: Q-function and value function!

Intuitively, we are happy with an action  $a_t$  in a state  $s_t$  if  $Q^\pi(s_t, a_t) - V^\pi(s_t)$  is large. On the contrary, we are unhappy with an action if it's small.

Using this, we get the estimator: 
$$\nabla_\theta J(\theta) \approx \sum_{t \geq 0} (Q^{\pi_\theta}(s_t, a_t) - V^{\pi_\theta}(s_t)) \nabla_\theta \log \pi_\theta(a_t | s_t)$$

# Actor-Critic Algorithm

**Problem:** we don't know Q and V. Can we learn them?

**Yes**, using Q-learning! We can combine Policy Gradients and Q-learning by training both an **actor** (the policy) and a **critic** (the Q-function).

- The actor decides which action to take, and the critic tells the actor how good its action was and how it should adjust
- Also alleviates the task of the critic as it only has to learn the values of (state, action) pairs generated by the policy
- Can also incorporate Q-learning tricks e.g. experience replay
- **Remark:** we can define by the **advantage function** how much an action was better than expected

$$A^\pi(s, a) = Q^\pi(s, a) - V^\pi(s)$$

# Actor-Critic Algorithm

Initialize policy parameters  $\theta$ , critic parameters  $\phi$

**For** iteration=1, 2 ... **do**

    Sample  $m$  trajectories under the current policy

$\Delta\theta \leftarrow 0$

**For**  $i=1, \dots, m$  **do**

**For**  $t=1, \dots, T$  **do**

$$A_t = \sum_{t' \geq t} \gamma^{t'-t} r_t^i - V_\phi(s_t^i)$$

$$\Delta\theta \leftarrow \Delta\theta + A_t \nabla_\theta \log(a_t^i | s_t^i)$$

$$\Delta\phi \leftarrow \sum_i \sum_t \nabla_\phi ||A_t^i||^2$$

$$\theta \leftarrow \alpha \Delta\theta$$

$$\phi \leftarrow \beta \Delta\phi$$

**End for**

# REINFORCE in action: Recurrent Attention Model (RAM)

**Objective:** Image Classification

Take a sequence of “glimpses” selectively focusing on regions of the image, to predict class

- Inspiration from human perception and eye movements
- Saves computational resources => scalability
- Able to ignore clutter / irrelevant parts of image

**State:** Glimpses seen so far

**Action:** (x,y) coordinates (center of glimpse) of where to look next in image

**Reward:** 1 at the final timestep if image correctly classified, 0 otherwise

*[Mnih et al. 2014]*

# REINFORCE in action: Recurrent Attention Model (RAM)

**Objective:** Image Classification

Take a sequence of “glimpses” selectively focusing on regions of the image, to predict class

- Inspiration from human perception and eye movements
- Saves computational resources => scalability
- Able to ignore clutter / irrelevant parts of image

**State:** Glimpses seen so far

**Action:** (x,y) coordinates (center of glimpse) of where to look next in image

**Reward:** 1 at the final timestep if image correctly classified, 0 otherwise

Glimpsing is a non-differentiable operation => learn policy for how to take glimpse actions using REINFORCE  
Given state of glimpses seen so far, use RNN to model the state and output next action

# Competing against humans in game play

## AlphaGo [DeepMind, Nature 2016]:

- Required many engineering tricks
- Bootstrapped from human play
- Beat 18-time world champion Lee Sedol

## AlphaGo Zero [Nature 2017]:

- Simplified and elegant version of AlphaGo
- No longer bootstrapped from human play
- Beat (at the time) #1 world ranked Ke Jie

## Alpha Zero: Dec. 2017

- Generalized to beat world champion programs on chess and shogi as well

**Recent advances in more complex games, e.g.  
StarCraft (DeepMind) and Dota (OpenAI)**

This image is CC0 public domain

# Summary

- **Policy gradients**: very general but suffer from high variance so requires a lot of samples. **Challenge**: sample-efficiency
- **Q-learning**: does not always work but when it works, usually more sample-efficient. **Challenge**: exploration
- Guarantees:
  - **Policy Gradients**: Converges to a local minima of  $J(\theta)$ , often good enough!
  - **Q-learning**: Zero guarantees since you are approximating Bellman equation with a complicated function approximator
